

I'd like you to use my new web browser, Firetran! It renders HTML 10% faster than Firefox, but only if there is no JavaScript. You can recompile if you want JavaScript, but we don't show that in our performance tests. The character encoding is compiled in, for efficiency. It has a great plugin community—developers add code directly to the web browser core, guarded by a `#ifdef`. Some developers change things that I don't like, so they distribute their own version of Firetran. Naturally, users of those packages submit bug reports to me and I ignore them because I can't reproduce with my version. Proxy configuration is compiled in so you don't have to worry about run-time configuration dialogs, just edit a makefile and recompile. To keep you secure, the https version of Firetran cannot use http and vice-versa.
